wordsThe Joint Compound (Joint) is a fast growing, North America based, producer and distributor of advanced, high performance, high pressure, thermally stable and high performance elastomers and products to enhance and advance elastomer capabilities. These products can be used as substitutes for more traditional sealants and sealant systems which have failed to live up to their potential or in use due to limitations. Joint is currently the only brand that produces elastomers meeting the standards of ASTM, ISO, and UPCS.[Cognitive side effects of neuroleptics]. Cognitive side effects of neuroleptics are often reported by neuropsychiatric patients and are commonly attributed to their antipsychotic action. They are often underestimated by both psychiatrists and patients, and can be explained by the heterogeneity of neuroleptics, including a variety of pharmacological, behavioral and cognitive effects, and by the wide number of confounding factors in the assessment of cognitive function. To elucidate neuroleptic effects on cognition, the classical, "controlled" studies of the past can be contrasted with the recent use of cognitive tasks which are closer to the actual psychopharmacological situation. Memory and concentration are usually impaired by neuroleptics, and attentional abilities are generally improved. The neuroleptic-induced cognitive impairment is in general limited to the long term. However, some patients are more vulnerable, particularly at the beginning of treatment or in patients with cognitive deterioration. The impairment of attention in response to neuroleptic administration, which is observed in healthy volunteers as well as in patients with schizophrenia, cannot be replicated in non-schizophrenic volunteers by using dopaminergic compounds. However, there is converging evidence that dopamine D1 agonists induce impairments in cognitive performance in healthy subjects. The cognitive effects of neuroleptics are based on dopamine D1 receptor antagonism and are similar to the effects of the D1 receptor antagonist SCH 39166. In contrast, dopamine D2 receptor antagonists (except sulpiride) have no effect on cognitive performance and are often even beneficial. Neuroleptics with high dopamine D2 receptor affinity are associated with few cognitive side effects. Since neuroleptic-induced cognitive impairment is observed in all treated patients, it is probable that the relative impairment of cognitive performance is an intrinsic feature of psychosis. This condition, which is also observed in unmedicated patients, could result from a combination of genetic factors, such as dopamine receptor abnormalities, and individual vulnerabilities in the central nervous 82157476af
